

This project aims to analyze the factors that determine the market value of football players and to examine whether player performance metrics can be used to predict their market value.

The dataset will be obtained from publicly available sources on Kaggle, containing player statistics such as age, goals, assists, minutes played, and market value. The dataset consists of a large number of observations, providing sufficient data for statistical analysis and machine learning applications.

To enhance the dataset, additional features will be created through data enrichment. These include performance-based metrics such as goals per minute, assists per minute, and total contribution (goals + assists), as well as categorical variables such as age groups.

The project will involve data cleaning to handle missing values and inconsistencies, followed by exploratory data analysis to identify patterns and relationships between variables.

Hypothesis testing will be conducted to examine the impact of performance metrics on market value.

Finally, machine learning techniques, specifically regression models, will be applied to predict player market value based on the selected features. The results will be evaluated to determine which factors most significantly influence player valuation.
